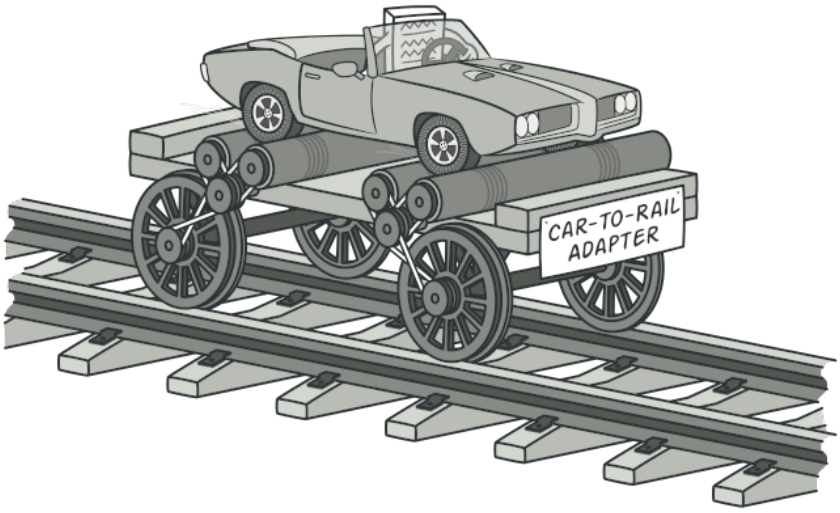
Adapter Pattern

Contents

1 Intent

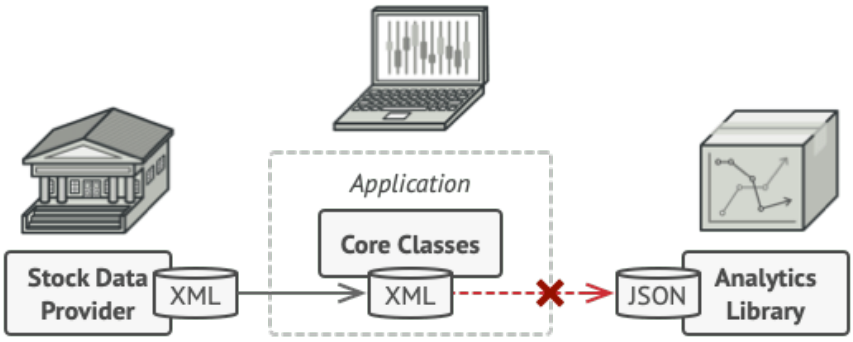
Adapter is a structural design pattern that allows objects with incompatible interfaces to collaborate.



2 Problem

Imagine that you're creating a stock market monitoring app. The app downloads the stock data from multiple sources in XML format and then displays nice-looking charts and diagrams for the user.

At some point, you decide to improve the app by integrating a smart 3rd-party analytics library. But there's a catch: the analytics library only works with data in JSON format.



You could change the library to work with XML. However, this might break some existing code that relies on the library. And worse, you might not have access to the library's source code in the first place, making this approach impossible.

3 Solution

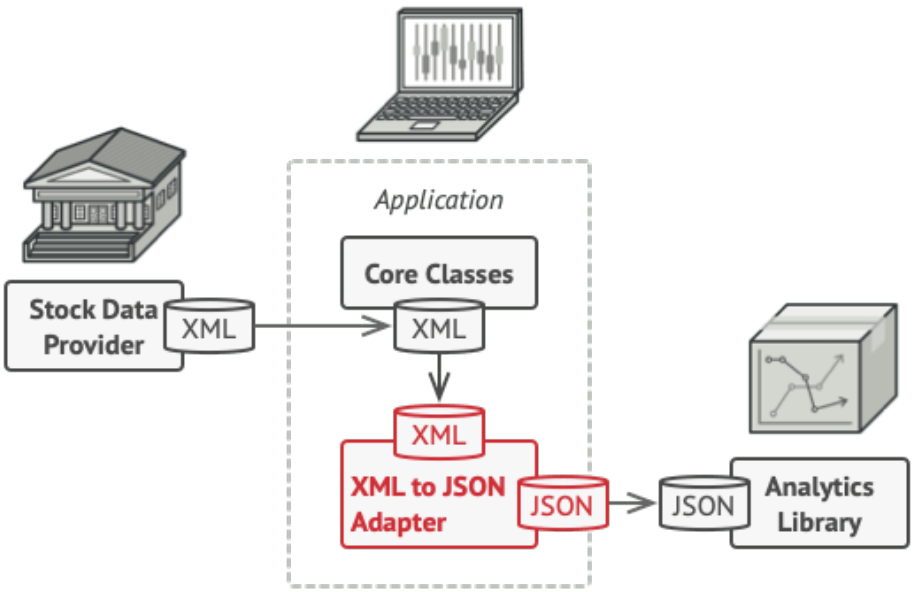
You can create an adapter. This is a special object that converts the interface of one object so that another object can understand it.

An adapter wraps one of the objects to hide the complexity of conversion happening behind the scenes. The wrapped object isn't even aware of the adapter. For example, you can wrap an object that operates in meters and kilometers with an adapter that converts all of the data to imperial units such as feet and miles.

Adapters can not only convert data into various formats but can also help objects with different interfaces collaborate. Here's how it works:

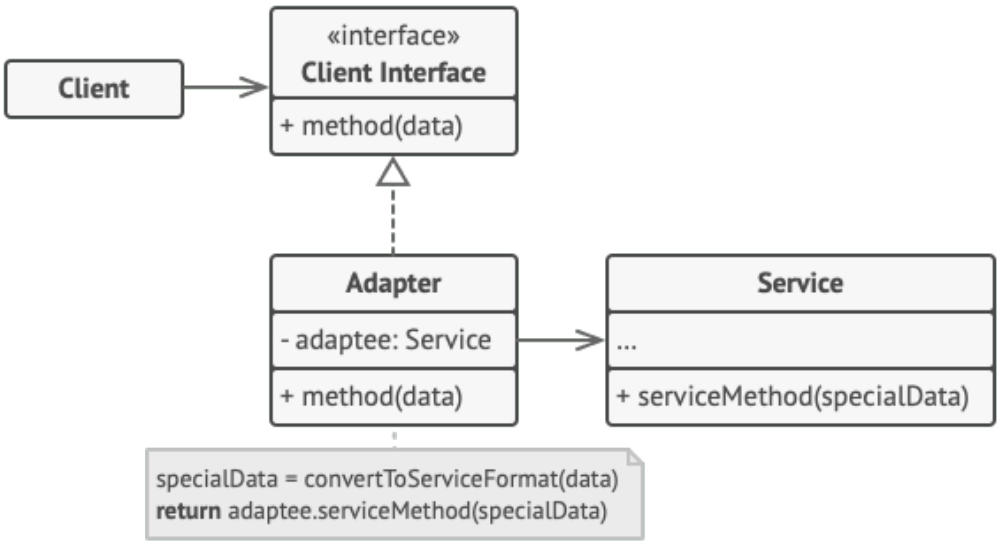
1. The adapter gets an interface, compatible with one of the existing objects.
2. Using this interface, the existing object can safely call the adapter's methods.
3. Upon receiving a call, the adapter passes the request to the second object, but in a format and order that the second object expects.

Sometimes it's even possible to create a two-way adapter that can convert the calls in both directions.



Let's get back to our stock market app. To solve the dilemma of incompatible formats, you can create XML-to-JSON adapters for every class of the analytics library that your code works with directly. Then you adjust your code to communicate with the library only via these adapters. When an adapter receives a call, it translates the incoming XML data into a JSON structure and passes the call to the appropriate methods of a wrapped analytics object.

4 Structure

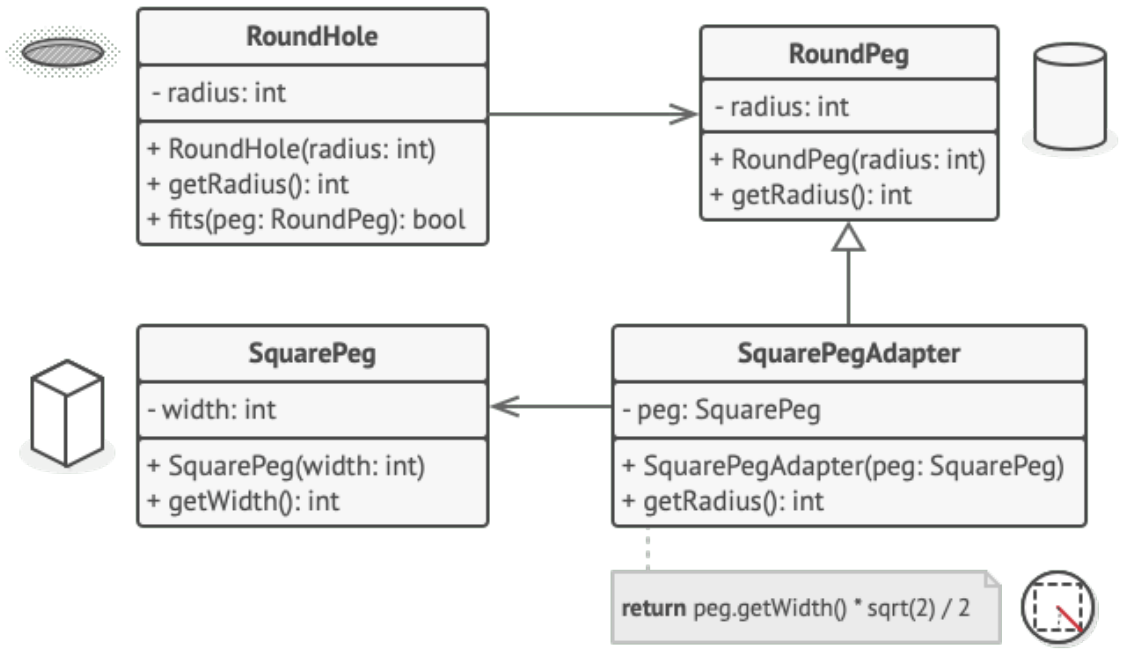


Structure of Adapter

1. The **Client** is a class that contains the existing business logic of the program.
2. The **Client Interface** describes a protocol that other classes must follow to be able to collaborate with the client code.
3. The **Service** is some useful class (usually 3rd-party or legacy). The client can't use this class directly because it has an incompatible interface.
4. The **Adapter** is a class that's able to work with both the client and the service: it implements the client interface, while wrapping the service object. The adapter receives calls from the client via the adapter interface and translates them into calls to the wrapped service object in a format it can understand.
5. The client code doesn't get coupled to the concrete adapter class as long as it works with the adapter via the client interface. Thanks to this, you can introduce new types of adapters into the program without breaking the existing client code. This can be useful when the interface of the service class gets changed or replaced: you can just create a new adapter class without changing the client code.

5 Pseudocode

This example of the Adapter pattern is based on the classic conflict between square pegs and round holes.



Adapting square pegs to round holes.

The Adapter pretends to be a round peg, with a radius equal to a half of the square's diameter (in other words, the radius of the smallest circle that can accommodate the square peg).

PSEUDO CODE

```
// Say you have two classes with compatible interfaces: RoundHole and RoundPeg.
class RoundHole is
  constructor RoundHole(radius) { ... }

  method getRadius() is
    // Return the radius of the hole.

  method fits(peg: RoundPeg) is
    return this.getRadius() >= peg.getRadius()

class RoundPeg is
  constructor RoundPeg(radius) { ... }

  method getRadius() is
    // Return the radius of the peg.

// But there's an incompatible class: SquarePeg.
class SquarePeg is
  constructor SquarePeg(width) { ... }

  method getWidth() is
    // Return the square peg width.

// An adapter class lets you fit square pegs into round holes.
//  It extends the RoundPeg class to let the adapter objects act as round pegs.
class SquarePegAdapter extends RoundPeg is
  // In reality, the adapter contains an instance of the SquarePeg class.
  private field peg: SquarePeg

  constructor SquarePegAdapter(peg: SquarePeg) is
    this.peg = peg

  method getRadius() is
    // The adapter pretends that it's a round peg with a radius
    //  that could fit the square peg that the adapter actually wraps.
    return peg.getWidth() * Math.sqrt(2) / 2

// Somewhere in client code.
hole = new RoundHole(5)
roundPeg = new RoundPeg(5)
hole.fits(roundPeg) // true

smallSquarePeg = new SquarePeg(5)
largeSquarePeg = new SquarePeg(10)
```

```
hole.fits(smallSquarePeg)  // this won't compile (incompatible types)

smallSquarePegAdapter = new SquarePegAdapter(smallSquarePeg)
largeSquarePegAdapter = new SquarePegAdapter(largeSquarePeg)
hole.fits(smallSquarePegAdapter) // true
hole.fits(largeSquarePegAdapter) // false
```

6 Applicability

1. Use the Adapter class when you want to use some existing class, but its interface isn't compatible with the rest of your code.
    - The Adapter pattern lets you create a middle-layer class that serves as a translator between your code and a legacy class, a 3rd-party class or any other class with a weird interface.
2. Use the pattern when you want to reuse several existing subclasses that lack some common functionality that can't be added to the superclass.
    - You could extend each subclass and put the missing functionality into new child classes. However, you'll need to duplicate the code across all of these new classes, which smells really bad.

      The much more elegant solution would be to put the missing functionality into an adapter class. Then you would wrap objects with missing features inside the adapter, gaining needed features dynamically. For this to work, the target classes must have a common interface, and the adapter's field should follow that interface. This approach looks very similar to the Decorator pattern.

7 How to Implement

1. Make sure that you have at least two classes with incompatible interfaces:
    - A useful service class, which you can't change (often 3rd-party, legacy or with lots of existing dependencies).
    - One or several client classes that would benefit from using the service class.
2. Declare the client interface and describe how clients communicate with the service.
3. Create the adapter class and make it follow the client interface. Leave all the methods empty for now.
4. Add a field to the adapter class to store a reference to the service object. The common practice is to initialize this field via the constructor, but sometimes it's more convenient to pass it to the adapter when calling its methods.

5. One by one, implement all methods of the client interface in the adapter class. The adapter should delegate most of the real work to the service object, handling only the interface or data format conversion.

6. Clients should use the adapter via the client interface. This will let you change or extend the adapters without affecting the client code.

8 Example

TODO

9 Exercises

1. Write code to demonstrate the program from the pseudocode.

2. Take an example about Adapter Pattern and write code to demonstrate the program.
